FILTERS

Why Use Filters

Protection

Filters help stop scratches and drops from damaging your lens' front glass element.

Alter Light

An ND filter decreases the amount of light that reaches your camera's sensor.

Reduce Reflections

A polarising filter can remove glare, haze and reflections in a scene.

Enhance Colors

You can enhance colors in a scene by using colored filters.

Types of Filters

Polarising

Eliminates glares and reflections, while darkening skies. They come in circular versions, that allow you to use different intensities.

Neutral Density

Blocks light evenly across the frame. These are available in many intensities, up to 10 stops.

Graduated ND

Blocks light across part of the frame. These are designed to darken the sky, while leaving the landscape untouched.

UV

Blocks or absorbs ultraviolet light. Film photographers use these filters, but they can cause lens flare, or lack of contrast.
